

# Basics of C++ in OpenFOAM

## Basics of C++ in OpenFOAM

#### **Prerequisites**

- You have some programming experience.
- You have experience in working in Linux.

#### Learning outcomes

- You will learn the basic syntax in C++
- You will learn how to use classes to implement simple C++ codes, and how member functions are called in the top-level code.
- You will learn how to implement functions in the top-level code, understand the difference between declaration and definition, and see how that can be practically used.
- You will learn how OpenFOAM compilation relates to compilation of a simple C++ code.

Note that you will be asked to pack up your final cleaned-up directories and submit them for assessment of completion.

## Basics of C++ in OpenFOAM

- To begin with: The aim of this part of the course is not to teach all of C++, but to give a short introduction that is useful when trying to understand the contents of OpenFOAM.
- After this introduction you should be able to *recognize* and make *minor modifications* to most C++ features in OpenFOAM.
- Some books:
  - C++ direkt by Jan Skansholm (ISBN 91-44-01463-5)
  - *C*++ *from the Beginning* by Jan Skansholm (probably similar)
  - C++ how to Program by Paul and Harvey Deitel
  - Object Oriented Programming in C++ by Robert Lafore
- A link:
  - https://www.geeksforgeeks.org/c-plus-plus/

#### C++ basics – types

• Variables can contain data of different *types*, for instance:

```
int myInteger;
for a declaration of an integer variable named myInteger, or
const int myConstantInteger = 10;
```

for a declaration of an constant integer variable named myConstantInteger with value 10.

- Variables can be added, substracted, multiplied and divided as long as they have the same type, or if the types have definitions on how to convert between the types.
- In C++ it is possible to define special *types* (classes), and there are many types defined for you in OpenFOAM.
- User-defined types must have the required conversions defined. Some of the types in Open-FOAM can be used together in arithmetic expressions, but not all of them.

# C++ basics – Namespace

- When using pieces of C++ code developed by different programmers there is a risk that the same name has been used for different things.
- By associating a declaration with a namespace, the declaration will only be visible if that namespace is used. The standard declarations are used by starting with:

```
using namespace std;
```

• OpenFOAM declarations belong to namespace Foam, so in OpenFOAM we use:

```
using namespace Foam;
```

to make all declarations in namespace Foam visible.

• Explicit naming in OpenFOAM:

```
Foam::function();
```

where function () is a function defined in namespace Foam. This must be used if any other namespace containing a declaration of another function () is also visible.

**CHALMERS** 

# C++ basics – input/output

• Input and output can be done using the standard library iostream, using:

```
cout << "Please type an integer!" << endl;</pre>
cin >> myInteger;
```

where << and >> are output and input operators, and endl is a manipulator that generates a new line (there are many other manipulators).

• In OpenFOAM a new output stream Info is however defined, and it is recommended to use that one instead since it takes care of write-outs for parallel simulations.

#### C++ basics, main function

• All C++ codes must have at least one function:

```
int main()
return 0;
```

in this case, main takes no arguments, but it may (as in OpenFOAM applications).

• Code appearing after the return statement is not executed!!!

```
In file basic1.C:
#include <iostream>
using namespace std;
int main()
int myInteger;
const int constantInteger=5;
const float constantFloat=5.1;
cout << "Please type an integer!" << endl;
cin >> myInteger;
cout << myInteger << " + " << constantInteger << " = "</pre>
     << myInteger+constantInteger << endl;</pre>
cout << myInteger << " + " << constantFloat << " = "</pre>
     << myInteger+constantFloat << endl;</pre>
return 0;
Compile and run with:
q++ basic1.C -o basic1;
./basic1
```

### C++ basics – operators

- +, -, \* and / are operators that define how the operands should be used.
- Other standard operators are:

```
응
       (integer division modulus)
       (add 1)
       (substract 1)
    (i+=2 adds 2 to i)
       (i-=2 subtracts 2 from i)
    (i \star = 2 multiplies i by 2)
      (i/=2 \text{ divides i by 2})
```

etc. User-defined types should define its operators.

- Comparing operators: < > <= >= != Generates bool (boolean)
- Logical operators: && || ! (or, for some compilers: and or not). Generates bool (boolean)

#### C++ basics – functions

- Mathematic standard functions are available in standard libraries. They are thus not part of C++ itself.
- Standard library cmath contains trigonometric functions, logaritmic functions and square root. (use #include cmath; if you need them)
- Standard library cstdlib contains general functions, and some of them can be used for arithmetics. (use #include cstdlib; if you need them)

### C++ basics – if, for and while-statements

• if-statements:

```
if (variable1 > variable2) { ... CODE ... } else { ... CODE ... }
```

• for-statements:

```
for (init; condition; change) { ... CODE ... }
```

• while-statements:

```
while (...expression...) {...CODE...}
```

break; breaks the execution of while

```
In file basic2.C:
#include <iostream>
#include <cmath>
using namespace std;
int main()
float myFloat;
cout << "Please type a float!" << endl;</pre>
cin >> myFloat;
cout << "sin(" << myFloat << ") = " << sin(myFloat) << endl;</pre>
if (myFloat < 5.5) {cout << myFloat << " is less than 5.5" << endl;} else
                   {cout << myFloat << " is not less than 5.5" << endl; };
for ( int i=0; i<myFloat; i++ ) {cout << "For-looping: " << i << endl;}
int j=0;
while (j<myFloat) {cout << "While-looping: " << j << endl; j++;}</pre>
return 0;
} //Note conversion of myFloat to int in loops!
Compile and run with:
g++ basic2.C -o basic2; ./basic2
```

#### C++ basics – arrays

• Arrays:

```
double f[5]; (Note: components numbered from 0!)
f[3] = 2.75; (Note: no index control!)
int a[6] = {2, 2, 5, 5, 0}; (declaration and initialization)
The arrays have strong limitations, but serve as a base for array templates
```

• Array templates (example vector. other: list, deque):

```
#include <vector>
using namespace std
```

The type of the vector must be specified upon declaration:

```
vector<double> v2(3); gives \{0, 0, 0\}
vector<double> v3(4, 1.5); gives {1.5, 1.5, 1.5}
vector<double> v4 (v3); Constructs v4 as a copy of v3 (copy-constructor)
```

• Array template operations: The template classes define member functions that can be used for those types, for instance: size(), empty(), assign(), push\_back(), pop\_back(), front(), clear(), capacity() etc. v.assign(4, 1.0); gives  $\{1.0, 1.0, 1.0, 1.0\}$ 

#### In file basic3.C:

```
#include <iostream>
#include <vector>
using namespace std;
int main()
vector<double> v2(3);
vector<double> v3(4, 1.5);
vector<double> v4(v3);
cout << "v2: (" << v2[0] << "," << v2[1] << "," << v2[2] << ")" << endl;
cout << "v3: (" << v3[0] << "," << v3[1] << "," << v3[2] << "," << v3[3] << ")" << endl;
cout << "v4: (" << v4[0] << "," << v4[1] << "," << v4[2] << "," << v4[3] << ")" << endl;
cout << "v2.size(): " << v2.size() << endl;</pre>
return 0;
//LineToFixCopyPasteProblem-----
```

#### Compile and run with:

```
q++ basic3.C -o basic3; ./basic3
```

Note that the standard vector class is **not** implemented to be able to execute:

```
cout << "v2: " << v2 << endl;
```

Such functionality is available in OpenFOAM.

## C++ basics – function implementation

• Example function named average

```
double average (double x1, double x2)
{
  int nvalues = 2;
  return (x1+x2)/nvalues;
}
```

takes two arguments of type double, and returns type double. The variable nvalues is a local variable, and is only visible inside the function. Note that any code after the return statement will not be executed.

- A function doesn't have to take arguments, and it doesn't have to return anything (the output type is then specified as void).
- There may be several functions with the same names, as long as there is a difference in the arguments to the functions the number of arguments or the types of the arguments.
- Functions must be *declared* before they are used.

```
In file basic4.C:
#include <iostream>
using namespace std;
double average (double x1, double x2)
  int nvalues = 2;
  return (x1+x2)/nvalues;
int main()
double d1=2.1;
double d2=3.7;
cout << "Average: " << average(d1,d2) << endl;</pre>
return 0;
Compile and run with:
q++ basic4.C -o basic4; ./basic4
```

#### C++ basics – declaration and definition of functions

• The function declaration must be done before it is used, but the function definition can be done after it is used. Example:

```
double average (double x1, double x2); //Declaration
main ()
  mv = average(value1, value2)
double average (double x1, double x2) //Definition
  return (x1+x2)/2;
```

The argument names may be omitted in the declaration.

• Declarations are often included from include-files:

```
#include "file.h"
#include <standardfile>
```

• A good way to program C++ is to make files in pairs, one with the declaration, and one with the definition. This is done throughout OpenFOAM.

```
In file basic5.C:
#include <iostream>
#include "basic5.H"
using namespace std;
int main()
double d1=2.1;
double d2=3.7;
cout << "Average: " << average(d1,d2) << endl;</pre>
return 0;
double average (double x1, double x2)
  int nvalues = 2;
  return (x1+x2)/nvalues;
In file basic5.H:
double average (double, double);
Compile and run with: q++ basic5.C -o basic5; ./basic5
```

## C++ basics – function parameters / arguments reference and default value

• If an argument variable should be changed inside a function, the type of the argument must be a reference, i.e.

```
void change(double& x1)
```

The reference parameter x1 will now be a reference to the argument to the function instead of a local variable in the function. (standard arrays are always treated as reference parameters).

• Reference parameters can also be used to avoid copying of large fields when calling a function. To avoid changing the parameter in the function it can be declared as const, i.e. void checkWord(const string& s) This often applies for parameters of class-type, which can be large.

• Default values can be specified, and then the function may be called without that parameter, i.e.

```
void checkWord(const string& s, int nmbr=1)
```

```
In file basic6.C:
#include <iostream>
using namespace std;
double average (double x1, double x2, int nvalues=2)
  x1 = 7.5;
  return (x1+x2)/nvalues;
int main()
double d1=2.1;
double d2=3.7;
cout << "Modified average: " << average(d1,d2) << endl;</pre>
cout << "Half modified average: " << average(d1,d2,4) << endl;
cout << "d1: " << d1 << ", d2: " << d2 << endl;
return 0;}
```

Compile and run with: q++ basic6.C -o basic6; ./basic6

#### C++ basics – Pointers

• Pointers point at a memory location (while a reference is referring to another variable, as shown before, i.e. they are different). Example (in basic 7.C):

```
#include <iostream>
using namespace std;
int main()
double d1=2.1;
double d2=3.7;
double* d3; //d3 is a pointer, currently not pointing at anything
d3 = \&d1; //Now d3 points at the memory location of d1
cout << "d1: " << d1 << endl;
cout << "d2: " << d2 << endl;
cout << "d3: " << d3 << endl;
cout << "*d3: " << *d3 << endl;
d3 = \&d2; //Now d3 points at the memory location of d2
cout << "d3: " << d3 << endl;
cout << "*d3: " << *d3 << endl;
return 0;}
```

Compile and run with: q++ basic7.C -o basic7; ./basic7

#### Pointers for turbulence models

• Turbulence models are treated with the turbulence pointer in OpenFOAM.

```
In file: $FOAM_SOLVERS/incompressible/simpleFoam/createFields.H:
autoPtr<incompressible::turbulenceModel> turbulence
    incompressible::turbulenceModel::New(U, phi, laminarTransport)
);
In file $FOAM SOLVERS/incompressible/simpleFoam/simpleFoam.C:
turbulence->correct();
```

#### C++ basics – Types

- Types define what values a variable may obtain, and what operations may be made on the variable.
- Pre-defined C++ types are:

signed char unsigned int unsigned long int short int float int unsigned char double unsigned short int long double

- User defined types can be defined in *classes*. OpenFOAM provides many types/classes that are useful for solving partial differential equations.
- OpenFOAM classes are used by including the class declarations in the header of the code, and linking to the corresponding compiled OpenFOAM library at compilation.
- The path to included files that are in another path than the current directory must be specified by -I
- The path to libraries that are linked to is specified with -L

#### In file basic8.C:

```
#include <iostream>
                       //Just for cout
using namespace std;
                       //Just for cout
#include "tensor.H"
                        //From OpenFOAM
#include "symmTensor.H" //From OpenFOAM
using namespace Foam;
                        //From OpenFOAM
int main()
   tensor t1(1, 2, 3, 4, 5, 6, 7, 8, 9); //From OpenFOAM
    cout << "t1[0]: " << t1[0] << endl;</pre>
    symmTensor st1(1, 2, 3, 4, 5, 6); //From OpenFOAM
    cout << "st1[5]: " << st1[5] << endl;</pre>
    return 0;
```

Make sure that you have sourced OpenFOAM in your terminal window. Compile and run with (some trial-and-error, looking at output from wmake for test/tensor):

```
g++ -std=c++0x basic8.C -DWM_DP -DWM_LABEL_SIZE=32 -I$FOAM_SRC/OpenFOAM/lnInclude \
    -L$WM PROJECT DIR/lib/$WM OPTIONS/libOpenFOAM.so -o basic8; ./basic8
```

Here, -DWM DP is for double precision floats and -DWM LABEL SIZE=32 is for 32 bit int. We include header files (declarations) from \$FOAM\_SRC/OpenFOAM/lnInclude We link to library (definitions) \$WM\_PROJECT\_DIR/lib/\$WM\_OPTIONS/libOpenFOAM.so
